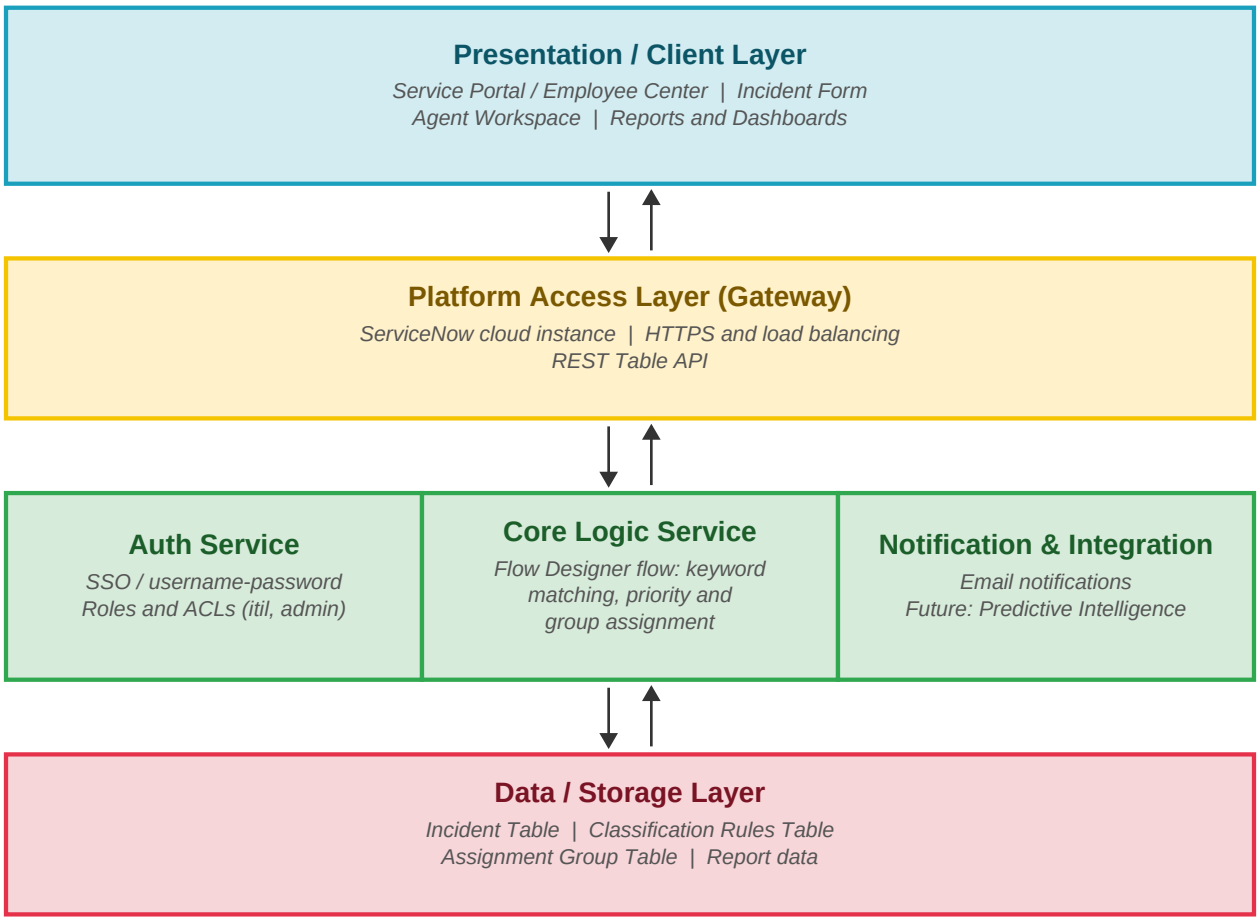
Solution Architecture

Date	29 September 2026
Team ID	SWTID-2026-6564
Project Name	Auto Ticket Classification using Flow Designer
Maximum Marks	5 Marks

Solution Architecture Diagram:

Provide a high-level visual representation of your solution's architecture. The layout below maps the Presentation Layer, Application Layer, and Data Layer for Auto Ticket Classification using Flow Designer.



Component Description Table

Component Name	Description / Role in Architecture	Technologies Used
Presentation Layer	Where employees raise tickets and agents work on them. Shows the incident form, ticket status and dashboards.	Service Portal / Employee Center, Incident Form, Agent Workspace
Platform Access Layer (API Gateway)	Receives every request securely and passes it to the platform services. Load balancing and availability are managed by ServiceNow.	ServiceNow cloud instance, HTTPS, REST Table API
Auth Service	Confirms who the user is and controls what each role can see or change.	SSO or username-password, Roles, ACLs
Core Logic Service (Microservice equivalent)	Runs when an incident is created. Matches keywords, sets category, subcategory and priority, assigns the group, and sends unmatched tickets to triage.	Flow Designer, server-side JavaScript
Notification & Integration	Informs the caller and the assignment group. Can be extended with machine-learning classification later.	Email Notifications; future: Predictive Intelligence
Database	Stores incidents, keyword rules and group mapping, and provides data for reports.	ServiceNow database: Incident, Classification Rules and User Group tables

How a Ticket Moves Through the Architecture

1. The employee submits an incident through the Service Portal.
2. The request reaches the platform over HTTPS after authentication.
3. The incident is saved in the Incident table, which triggers the flow.
4. The flow reads the keyword rules and group mapping, then updates the incident.
5. Notifications go to the caller and the assignment group, and dashboards read the same data.
